

# Bericht zum spitalbasierten COVID-19-Sentinel- Überwachungssystem

**Datenstand: 25. Juli 2022**

## 1. Einleitende Zusammenfassung

Das spitalbasierte COVID-19-Sentinel-Überwachungssystem (CH-SUR) wurde im Jahr 2018 gegründet, um grippebedingte Hospitalisationen zu erfassen. Bereits am 1. März 2020, vier Tage nach der Meldung des ersten bestätigten COVID-19 Falls in der Schweiz, stand das angepasste Programm bereit, um auch Hospitalisationen im Zusammenhang mit einer laborbestätigten SARS-CoV-2-Infektion zu registrieren.

Zurzeit nehmen 20 Spitäler aktiv teil, darunter die meisten Kantons- und Universitätsspitäler, welche einen grossen Teil der hospitalisierten pädiatrischen und erwachsenen Patientinnen und Patienten in der ganzen Schweiz abdecken. Die CH-SUR-Statistik gibt unter anderem die Anzahl und Dauer der **Hospitalisationen** sowie die Aufenthalte auf der Intensivpflegestation an. Eine Patientin oder ein Patient kann während einer Hospitalisationsepisode mehrfach hospitalisiert werden bzw. mehrere Aufnahmen in eine Intensivpflegestation (**IPS**) benötigen. Ersichtlich ist in CH-SUR ebenfalls, ob die Patientin oder der Patient während der Hospitalisation **an oder mit COVID-19** verstorben ist.

Einschlusskriterien: CH-SUR erfasst Daten von Patientinnen und Patienten, welche mit einer dokumentierten Infektion mit SARS-CoV-2 hospitalisiert wurden und deren Spitalaufenthalt länger als 24 Stunden andauert. **Nosokomiale** SARS-CoV-2-Infektionen werden in der Datenbank ebenfalls erfasst und in einem separaten Kapitel am Schluss dieses Berichts aufgeführt. Als Bestätigung für eine Infektion gilt ein positiver PCR-Test (Polymerase Chain Reaction) oder ein positiver Antigen-Schnelltest, wie auch ein klinischer Befund für COVID-19.

Seit Beginn der Epidemie bis zum 24. Juli 2022 wurden Daten von 35 922 **Hospitalisationsepisoden** erhoben. Im gleichen Zeitraum wurden dem BAG im Rahmen der Meldepflicht für die gesamte Schweiz 56 027 Episoden von Hospitalisationen mit einer laborbestätigten SARS-CoV-2-Infektion gemeldet. Das CH-SUR-System deckte somit ca. 64,1% aller gemeldeten Hospitalisationen im Zusammenhang mit SARS-CoV-2 in der Schweiz ab.

Seit März 2022 konzentriert sich dieser Bericht auf Episoden, bei welchen die Infektion ausserhalb des Spitals stattgefunden hat (**ambulant erworbene** Infektionen, beschrieben in Kapitel 2 bis 6). Ein separates Kapitel befasst sich mit den **nosokomialen** Infektionen (Kapitel 7). Der Gesamtanteil der nosokomialen Infektionen unter allen dokumentierten Episoden lag bei 14,6% (5 248 von 35 922), während der Anteil der Episoden im Zusammenhang mit ambulant erworbenen Infektionen 82,1% (29 484 von 35 922) betrug (Abbildung 1). 3,3% der Episoden konnten weder den nosokomialen noch den ambulant erworbenen Infektionen zugeordnet werden.

Von allen Episoden im Zusammenhang mit einer ambulant erworbenen Infektion, für welche vollständige relevante Daten vorliegen, erforderten 14,5% einen Aufenthalt in einer IPS (4 074 von 26 709 Episoden, 26. Februar 2020 bis Mai 31, 2022) und 9,1% führten zum Tod an COVID-19 (2 442 von 26 709 Episoden, 26. Februar 2020 bis July 24, 2022).

Während des letzten Zeitraums, für den genügend Daten vorliegen (Apr 01, 2022 bis Mai 31, 2022), wurden 1 412 Episoden im Zusammenhang mit ambulant erworbenen Infektionen verzeichnet. Davon betrafen 360 (25,5%) nicht

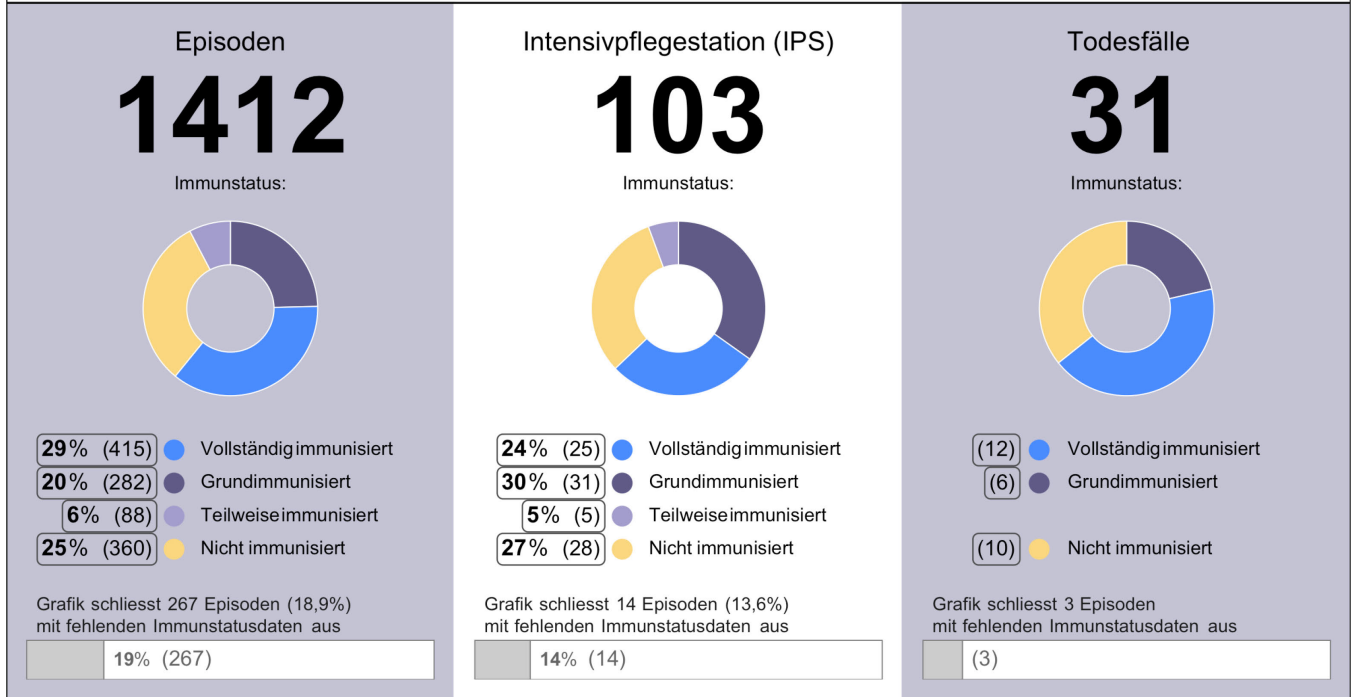

immunisierte Patientinnen und Patienten und 415 (29,4%) **vollständig immunisierte** Patientinnen und Patienten (Abbildung 2). Im gleichen Zeitraum waren 103 Episoden mit einem Aufenthalt auf einer Intensivpflegestation verbunden. Von diesen betrafen 28 (27,2%) nicht immunisierte und 25 (24,3%) vollständig immunisierte Patientinnen und Patienten. In 31 Episoden starben die Patientinnen und Patienten an COVID-19 (2,2% aller registrierten Episoden mit bekanntem Outcome), wobei 10 Todesfälle nicht immunisierte Patientinnen und Patienten und 12 vollständig immunisierte Patientinnen und Patienten betrafen.

Am 1. April 2022 kehrte die Schweiz in die normale Lage zurück. Seither besteht die Teststrategie in den Spitälern darin, nur noch Patienten mit Symptomen, welche mit einer SARS-CoV-2-Infektion vereinbar sind, zu testen. Diese Änderung der Teststrategie kann zu einer Verringerung der Zahl der registrierten Fälle führen, da nur noch Patienten mit typischen COVID-19-Symptomen identifiziert werden. Definitionen und weitere Informationen zu den Daten finden Sie im Kapitel **Glossar und ergänzende Informationen** am Schluss dieses Berichts.

**Abbildung 1:** Episoden nach Fallklassifizierung (Infektionsquelle). Anteil (normalisiert in %) der Episoden nach Infektionsquelle (Diagramm a) und absolute Anzahl Episoden über die Zeit (Diagramm b). Bei Episoden mit Mehrfachhospitalisation wurde die Fallklassifizierung der Ersthospitalisation berücksichtigt. Aufgrund von Verzögerungen bei der Datenerfassung werden die Daten der letzten beiden Monate (grau markiert) als provisorisch betrachtet.

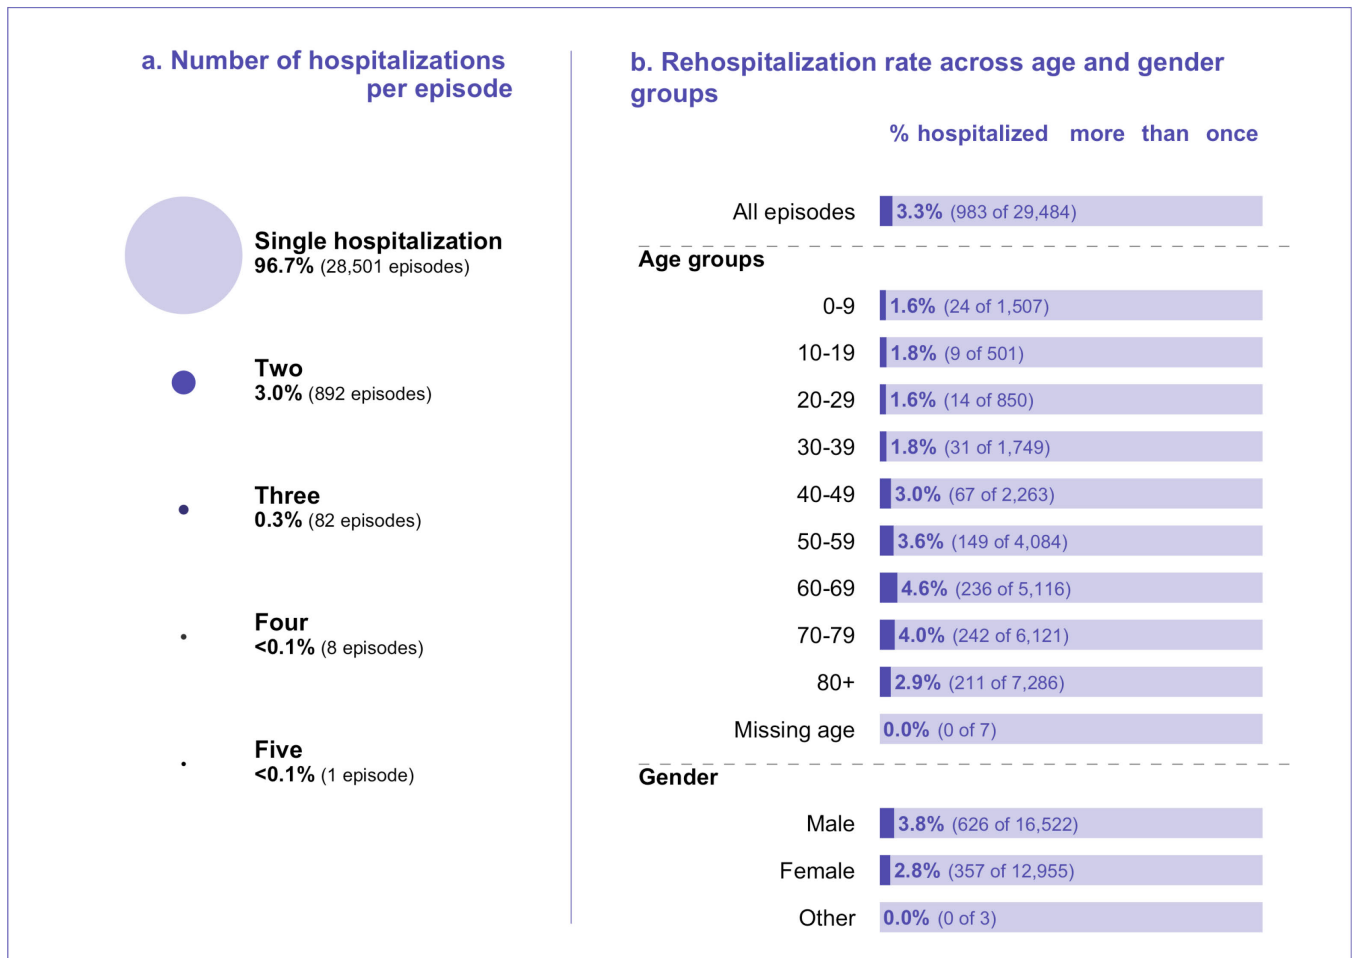

Übersicht über CH-SUR Hospitalisierte, in den IPS behandelte Episoden und Todesfälle vom 01. April 2022 bis 31. Mai 2022

**Abbildung 2:** Übersicht über die neuesten Daten. Die Daten der letzten beiden Monate werden aufgrund von Verzögerungen bei der Dateneingabe als vorläufig betrachtet und wurden daher nicht berücksichtigt.

## 2. Hospitalizations and demographic characteristics

Between the start of the epidemic in Switzerland and July 24, 2022 and among the 19 hospitals actively participating in CH-SUR, 29,484 episodes of community acquired infections were registered, accounting for a total of 30,568 hospitalizations. There were more hospitalizations than episodes because some episodes include multiple hospitalizations (for more details see section glossary and supplemental information). An overview of these rehospitalizations is shown in Figure 3.

**Figure 3:** Hospitalizations per episode of hospitalization and rehospitalization rate across demographic groups. Includes records between March 2020 and July 24, 2022.

Most patients (96.7% [28,501 of 29,484]) were hospitalized only once during an episode, while 3% of the registered episodes (982 of 29,484) included two to four hospitalizations. Only one episode included five hospitalizations (Figure 3b).

The overall rate of rehospitalization within the same episode was 3.3% (983 of 29,484) (Figure 3c). The 60-69 age group and the 70-79 age group had the highest rate of rehospitalization at respectively 4.6% (236 of 5,116) and 4.0% (242 of 6,121). Men had a higher rehospitalization rate than women, 3.8% (626 of 16,522) vs 2.8% (357 of 12,955) respectively.

Among all episodes with community acquired infections, the majority (56% [16,522 of 29,484]) of the episodes concerned male patients (Figure 4a), and the age distribution was skewed towards older persons (Figure 4b). The largest age category corresponded to patients aged 80 and above (25.0% [7,286]).

Figures 4c and 4d show the gender and age distribution ratio over time. Except for January and April 2022, more men than women were admitted in each month for the entire period of observation. The proportion of episodes concerning patients aged 50 and above was notably high between October 2020 and January 2021, with a peak in November 2020: 88.3% (2,813 of 3,186) of the episodes of patients admitted in this month concerned patients 50 years old and above (Figure 4d). This peak in older age admissions mirrors a similarly-timed peak in admission

severity and case fatality ratios described later. An increase in the percentage of episodes of patients aged 50 and above was observed again from September 2021 to November 2021, reaching a local peak of 75.3% (816 of 1,083) in November 2021. Over the month of May 2022, 80.6% (312 of 387) of episodes concerned patients aged 50 and above. Notably, in this last period, we are seeing an increase in the elderly population being admitted with 27.1% [105 of 387] of episodes pertaining to patients aged between 70 and 80 years old and 37.2% [381 of 1,025] of episodes pertaining to patients over 80 years old.

**Figure 4:** Demographic characteristics: gender and age distribution of admitted hospitalized patients, overall and per month. For episodes with multiple hospitalizations, the admission date of the first hospitalization was used. Data

*from the last two months (highlighted gray) is considered provisional due to entry delays. The 'other' gender category was removed from panel c, and the missing age group was removed from panel d.*

## 3. Outcomes

### 3.1. Outcomes overview

Figure 5 shows the final outcomes of CH-SUR episodes with **community acquired** infections over three time intervals. **Episodes** resulting in death, for which COVID-19 was the **cause of death** (died *of* COVID-19) are shown separately from those with a different cause of death (died *with* COVID-19, but not *of* COVID-19). A medical doctor at the hospital for each CH-SUR-participating center determined of whether a patient died of COVID or another cause. Episodes where the cause of death was not certain, but there was a COVID-19 diagnosis (in conformity for complete inclusion criteria for CH-SUR) were counted as died of COVID or suspected death of COVID. The outcome **“discharged”** includes patients who were transferred out of the CH-SUR system. Episodes with “pending or missing outcomes” correspond to either patients who were still hospitalized or whose outcomes were not yet recorded in the database at the date of data extraction. Because of the higher proportion of incomplete data during the most recent months, case fatality rates from these months should be interpreted with caution.

**Figure 5:** Outcomes for COVID-19 related episodes of hospitalization in CH-SUR hospitals. Includes records up to July 24, 2022. For episodes with multiple hospitalizations, only the final outcome is considered. Patients where the cause of death was not certain, but there was a COVID-19 diagnosis (in conformity for complete inclusion criteria for CH SUR) were counted as Died of COVID or suspected death of COVID. Data from the last two months (highlighted gray) is considered provisional due to entry delays. (\* Died of COVID as a confirmed or suspected cause of death)

## 3.2. Outcomes over time

Figure 6 shows the final outcomes of episodes linked to community acquired SARS-CoV-2 infections over time (Figure 6a & 6b) and the disease severity score at admission as a function of time (Figure 6c).

The first mortality peak is seen for patients admitted around the beginning of the epidemic: 15.1% (262 of 1,732) of episodes of patients first admitted in March 2020 resulted in death. Mortality decreased after March 2020, but rose again between October 2020 and January 2021, with a peak in December 2020: 13.8% (328 of 2,370) of episodes of patients first admitted in December 2020 resulted in death. An additional local peak of mortality was observed during the month October 2021, when 12.2% (53 of 433) of episodes resulted in death of COVID-19.

The high case fatality rates of patients with episodes of hospitalization in March 2020, between October 2020 and January 2021 and during October 2021, are mirrored by the higher admission severity scores (Figure 6c) and older patients' ages (Figure 4c) during these periods. Overall, in 31.7% (550 of 1,734) of the episodes with admission date in March 2020, the severity score was above 2. Over the months of October 2020 to January 2021, the proportion of episodes with severity scores of 2 and above was higher as over the rest of the epidemic, representing more than 40% (954 of 2,384) of the admissions in that period. Most recently, during May 2022, 36.2% (140 of 387) of the episodes had a severity score above 2, but this is not mirrored by higher case fatality rates (Figure 5)

**Figure 6:** Epidemic curve, episodes' outcomes and severity scores at admission for COVID-19 hospitalizations over time. Includes records up to July 24, 2022. Data from the two last months (highlighted in gray) are considered provisional due to data entry delays. Episodes where the cause of death was not certain, but there was a COVID 19 diagnosis (in conformity for complete inclusion criteria for CH SUR) were counted as Died of COVID or suspected death of COVID. (\* Died of COVID as a confirmed or suspected cause of death)

### 3.3. Case fatality rate (CFR) across demographic and risk groups

Since the beginning of the epidemic and until May 31, 2022, the case fatality rate (CFR) for **episodes with community acquired** infections increased with increasing age, from 0% (0 of 1,362) in episodes of patients aged 0-9, to 3.2% (121 of 3,748) in episodes of patients aged 50-59, and to 20.7% (1,256 of 6,081) in episodes of patients aged 80+. CFR% was greater in men than in women: 10.8% (1,597 of 14,740) vs 7.4% (829 of 11,254) respectively. In addition, the CFR% was greater for episodes with higher severity scores at admission: 1% (90 of 8,936) of the episodes with severity score 0 resulted in death of COVID-19, while 47.9% (23 of 48) of the episodes with severity score 5 resulted in death of COVID-19.

The overall CFR% of the most recent period for which enough data is available (months April and May 2022, Figure 7b) was lower than the CFR% of the whole epidemic period (3.2% vs. 9.3%). The CFR% of the age groups 70-79 and 80+ were also lower than over the whole epidemic (Figure 7).

Of note, there was no clear mortality difference across different BMI groups. Data regarding vaccination status can be found in section 4.

**a. All data: CFR % for 25,998 episodes with first hospitalization between Feb 26 2020 and May 31 2022**

**b. April & May: CFR % for 956 episodes with first hospitalization between Apr 01 2022 and May 31 2022**

**Figure 7: Case fatality rate (CFR) % among demographic and risk groups: percentage of hospitalization episodes in different demographic groups, which ended in the death of the patient of COVID-19 in hospital. Both figures include records up to May 31 2022 but records with incomplete data (ongoing hospitalization episodes or with a pending outcome in the database) were not included. Blank rows indicate a count of zero.**

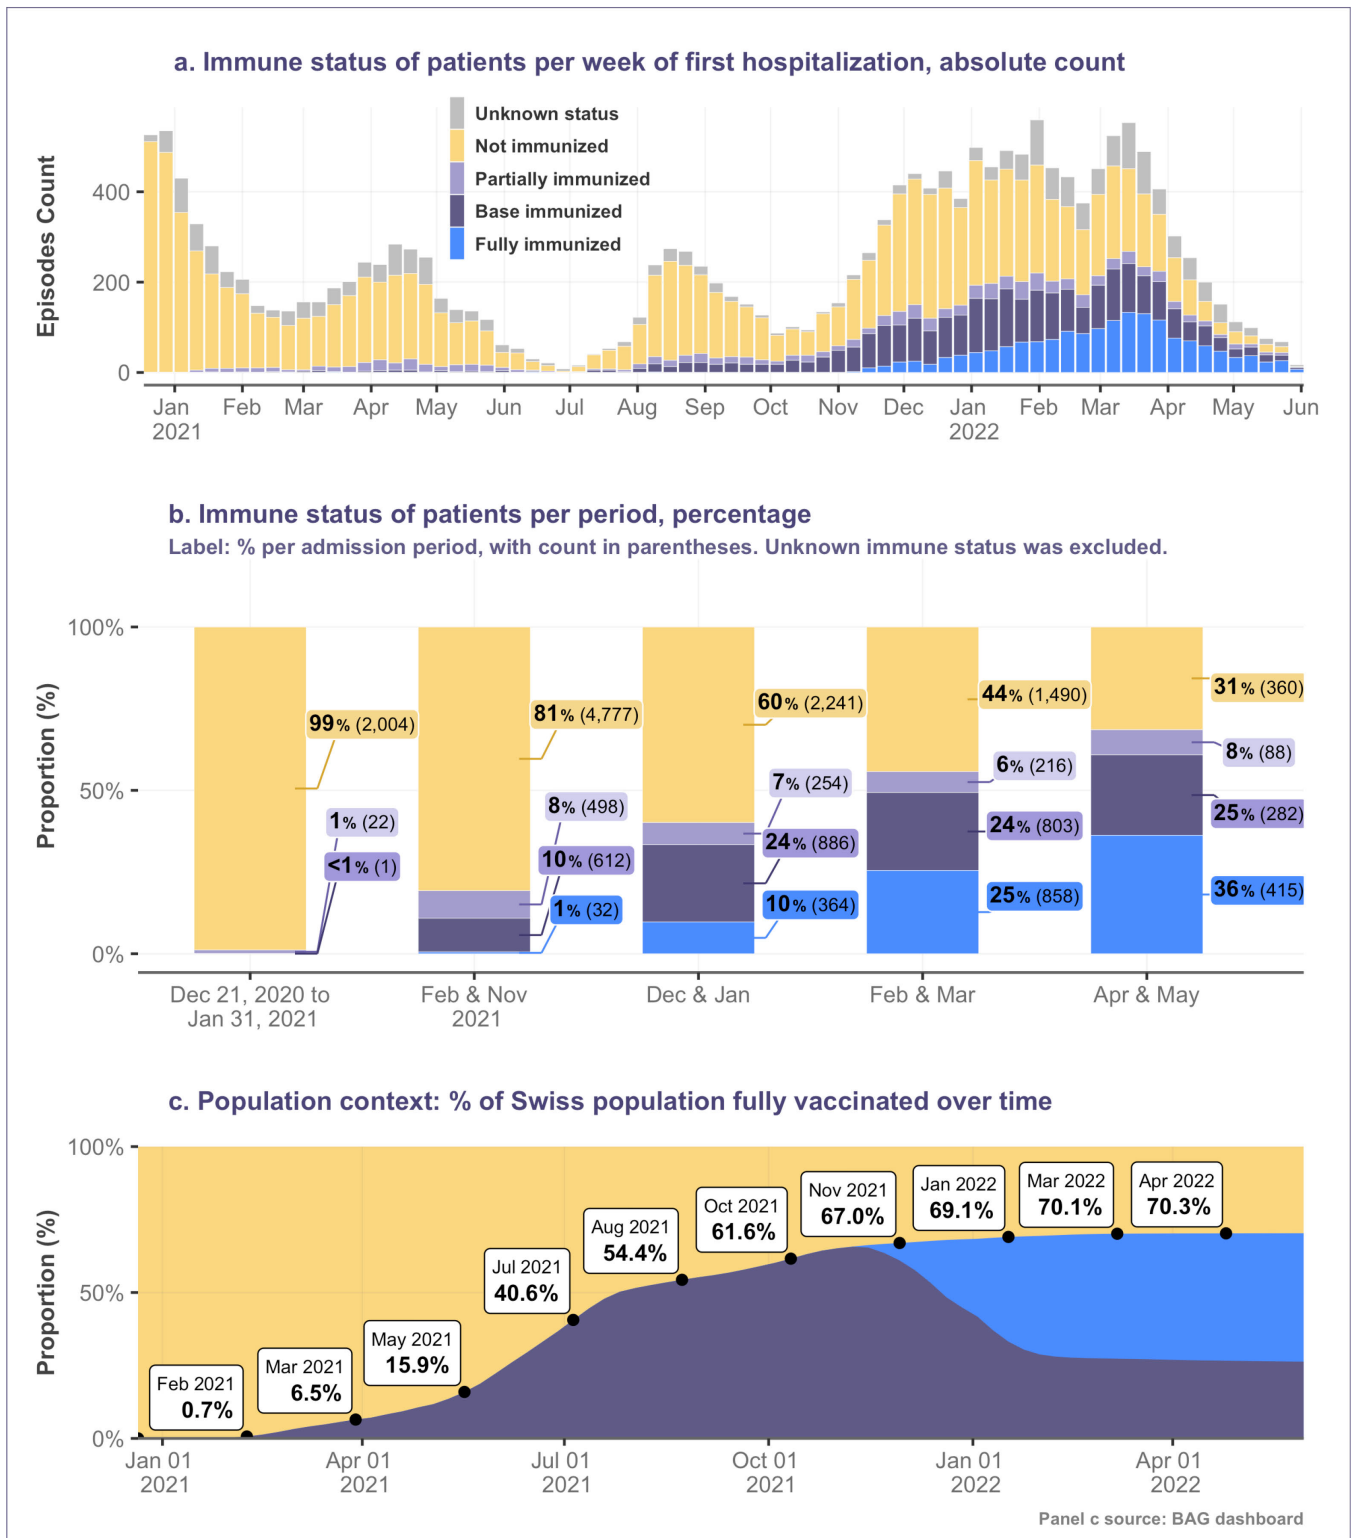

## 4. Immune/vaccination status

### 4.1. Immune status over time

For these analyses, the **immune status** of a patient considers the previous COVID-19 infections and the vaccine doses received up to the time of a positive COVID-19 test, specifically up to the time when the sample for the test was collected.

The proportion of **fully immunized** patients among **episodes** with **community acquired** infections rose gradually after January 2021 (Figure 8b). This is expected, given the rise in the proportion of the fully vaccinated Swiss population (Figure 8c, source: [FOPH Dashboard](#)).

During the months of May 2022, 70.3% of the Swiss population was fully vaccinated (Figure 8c). It is important to note that we can know the percentage of the population which is vaccinated (through administrative records), but only approximate the proportion of the population which is immunized. Recent studies from [Corona Immunitas](#) are indicating that **the population immunization (by vaccination and/or previous infection) is nearing the 100%**. The higher percentage of base immunized and fully immunized of recent months (24.6% and 36.2% respectively) within the episodes recorded in CH-SUR (Figure 8b), may therefore be partly linked to the decreasing number of non-immunized persons in the population.

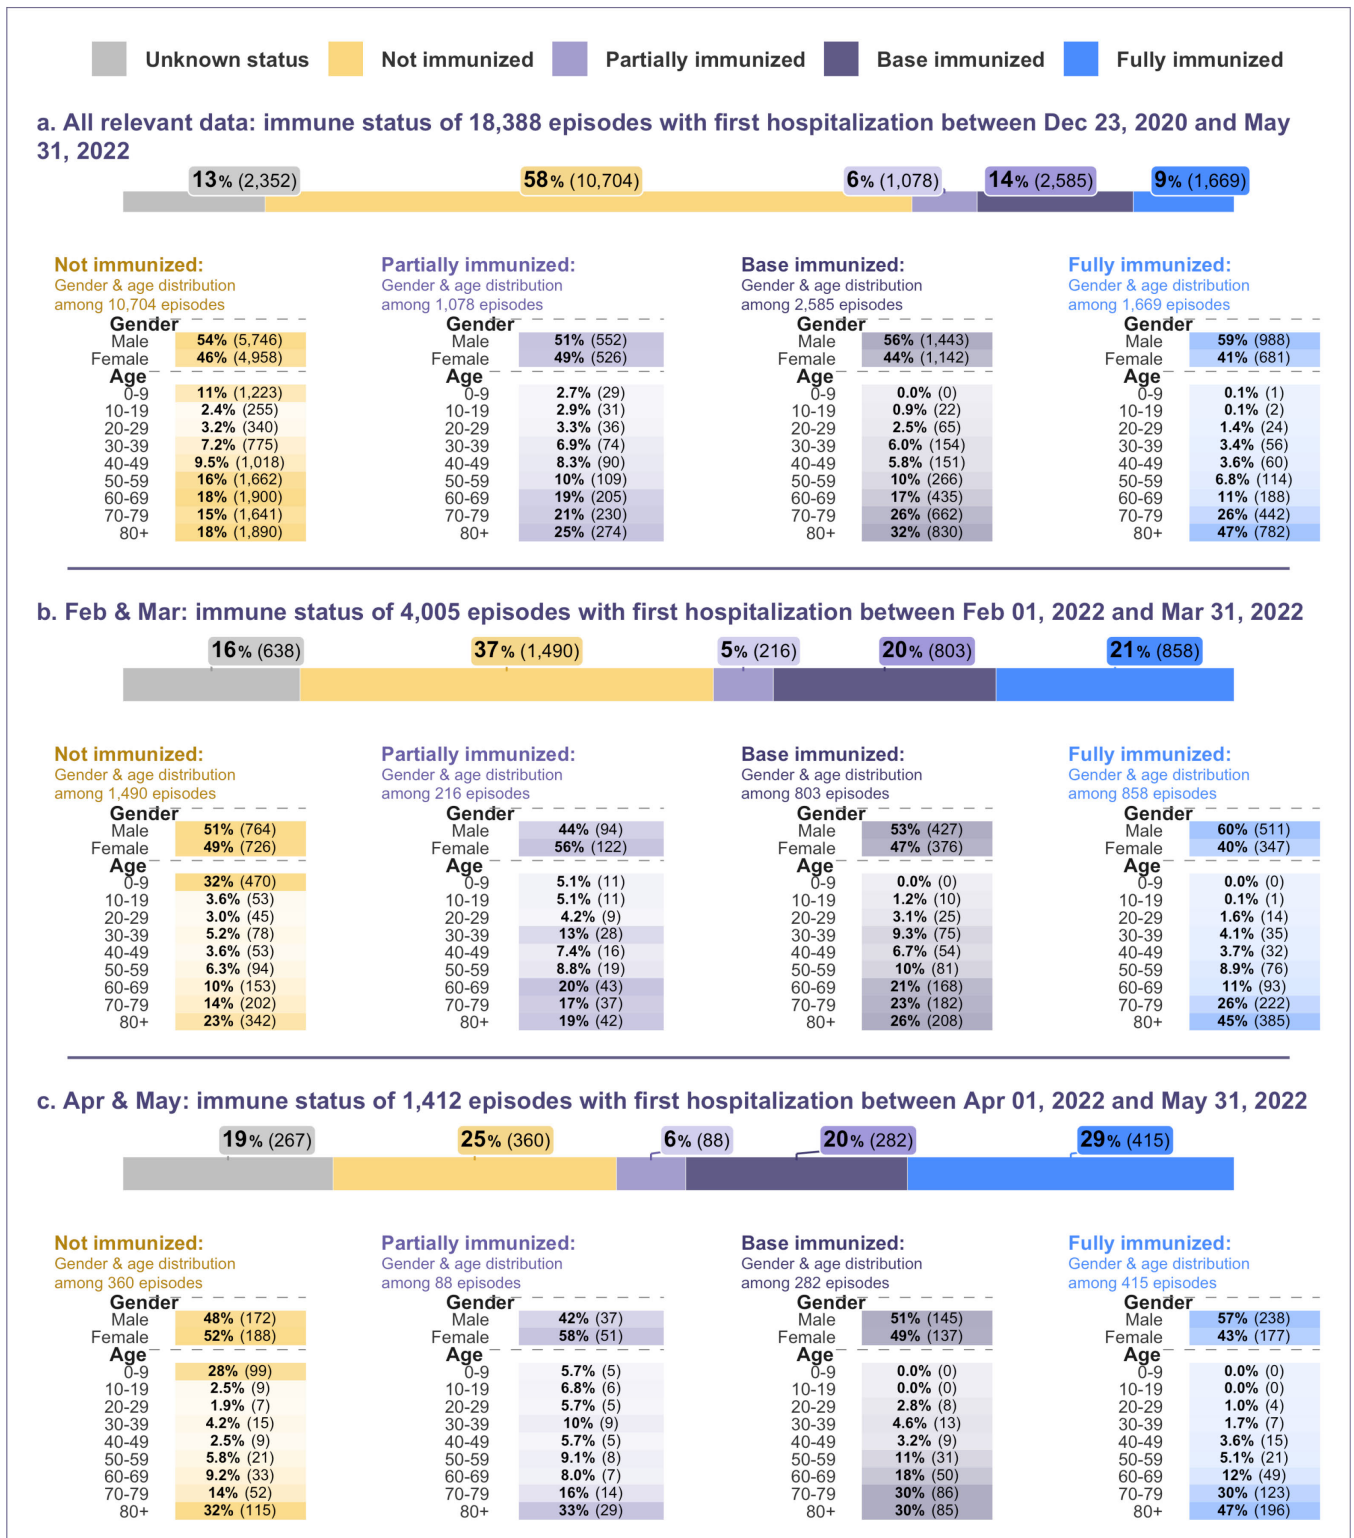

**Figure 8:** Immune status of patients and overall vaccination rate in Switzerland (exported: July 24, 2022). See glossary for definitions of immune status categories. For episodes with multiple hospitalizations, the immune status for the first hospitalization was considered. Panels a. and b. include episodes since the week vaccination began, Dec 21, 2020. (Vaccination began on Dec 23, 2020, but we include Dec 22 and 21 to cover a full week.) Episodes with first admission date after May 31, 2022 were excluded, as a large proportion of these records have not been completely filled in the database.

## 4.2. Demographic characteristics by immune status

**Fully immunized** hospitalized patients were disproportionately older. Since vaccination initiation, 47% of the episodes of fully immunized patients corresponded to patients aged 80 and above (Figure 9a, right panels). In contrast, only 18% (1,890 of 10,704) of the episodes of non-immunized patients corresponded to patients aged 80 and above (Figure 9a, left panel).

However, in more recent data, we see an augmentation in the proportion of older (aged 80+) as well as younger patients (0 to 9 years old) among the non-immunized episodes. From February 2022 to March 2022, among the episodes of non-immunized patients aged 0 to 9 years old, 32% (470 of 1,490) concerned patients aged 0 to 9 years old and 23% (342 of 1,490) concerned patients aged 80 and above. In the most recent data, from April 2022 to May 2022, 28% (99 of 360) of non-immunized episodes involved patients aged 0 to 9 years and 32% (115 of 360) involved patients aged 80 years and above.

**Figure 9:** Demographic characteristics of hospitalized patients by immune status, over three different periods. Some patients may be counted more than once, as a single patient can have several episodes. Episodes with first admission date after May 31 2022 were excluded, as a large proportion of these records have not been completely filled in the database. Episodes with missing ages or gender are not included in the analysis.

### 4.3. Outcomes by immune status

Since the date vaccinations began, December 23, 2020, among the 1,368 episodes of fully immunized patients (community acquired infections), CH SUR registered 63 deaths because of COVID-19 (Figure 10a, right panels: fully immunized). 44 of them corresponded to patients aged 80 years old and above. Over the same period, 745 episodes ended in COVID-caused deaths among non-immunized patients (Figure 10a, left panel).

During the months of April and May, CH-SUR registered 28 deaths due to COVID-19 of which the immune status was known. Of these, 10 (35.7%) happened among non-immunized patients, 0 deaths (0%) among partially immunized patients, 6 deaths (21.4%) among base immunized patients, and 12 deaths (42.9%) among fully immunized patients (Figure 10). This may be linked to the increasingly low number of non-immunized patients in the population (see section 4.1.)

However, the CFR values by age show that the risk of death for the limited number of people who are hospitalized despite full vaccination is lower than that of unvaccinated hospitalized people across all age groups. This is specifically true for episodes concerning patients aged over 80 (20.9% CFR for non-immunized episodes compared to 7.0% for fully immunized episodes) (Figure 10c, left and right panel). This reflects the protective effect of vaccination on the risk of death.

**a. All relevant data: 1,057 deaths among 14,283 episodes with first hospitalization between Dec 23, 2020 and May 31, 2022**

**Not immunized:**  
Age distribution of 745 deaths  
in 9,825 episodes

Age	Cases	Deaths	CFR %
0-9	1155	0	0%

50-59	19	0	0%
60-69	39	0	0%
70-79	82	3	3.7%
80+	122	9	7.4%

**Figure 10:** Mortality of CH-SUR hospitalized patients by immune status, age group and hospitalization episode, over three different periods. The total counts of episodes in the subtitles include episodes with a final patient outcome known (discharged, died of any cause, or transferred out of CH-SUR), and where the patient's immune status was base immunized, fully immunized, partially immunized or not immunized. Episodes with missing age, missing gender, or missing were not included in the analysis. Counts of deaths only include episodes resulting in death because of COVID-19 (including those with COVID as suspected cause of death). Case-fatality rate (CFR), especially for the partially immunized and fully immunized categories, should be interpreted with caution due to small sample sizes.

## 5. Intensive care unit (ICU) admission

### 5.1. ICU admission over time

Figure 11 shows the proportion (in %) of ICU admission over time among episodes with community acquired infections. The proportion of episodes with ICU admissions peaked between May and July 2020. Notably, this was during a period of low overall hospitalizations. In contrast, the lowest proportion was observed in most recent months since January 2022.

**Figure 11:** Percentage and proportion of episodes with at least one ICU admission over time. Records with incomplete data (ongoing episodes or with a pending outcome in the database) were not included. Data from the last two months (highlighted gray) are considered provisional due to data entry delays.

## 5.2. ICU admission across demographic and risk groups

Over the whole period of observation, for **episodes** linked to **community acquired** infections, **ICU** admission probability across ages was roughly bimodal with a peak for the 10-19-year age group and for the 60-69 age group (Figure **12a**). The 60-69 age group had the highest probability of admission to the ICU, with 23.9% (1,179 of 4,942) of the episodes including at least one ICU admission. Notably, individuals aged 80 and above were least likely to be admitted to the ICU, with 5.3% (357 of 6,760) of the episodes including at least one ICU admission.

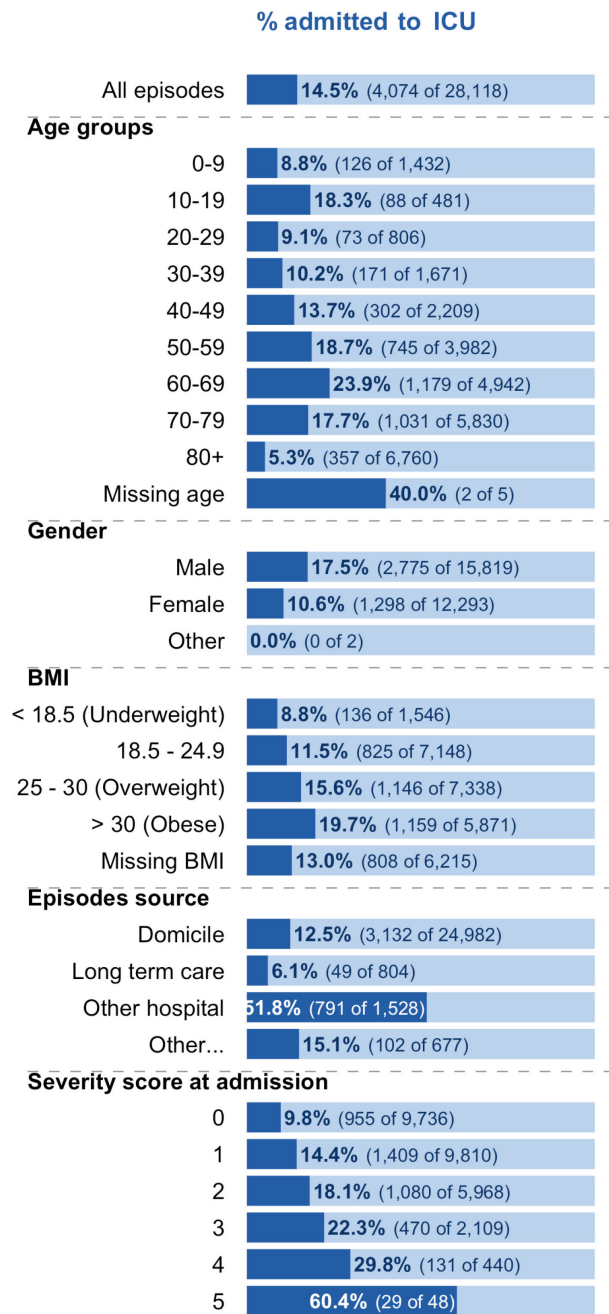

Males were more likely to be admitted to the ICU than females. Overall, admissions to the ICU were registered for 17.5% of the episodes concerning males, compared to 10.6% of the episodes concerning females.

Episodes of patients transferred from other hospitals had a high probability of ICU admission: 51.8% of such episodes (791 of 1,528) required at least one ICU admission (Figure **12a**), compared to an overall admission rate of 16.9% for all (community acquired) episodes.

ICU admission probability also increased slightly with increasing BMI and steeply with increasing admission **severity scores** (Figure **12a**).

Figure **12b** shows the ICU admissions for the most recent period with available data (April 2022 and May 2022). The distribution of ICU admissions across different population groups during the latest period was roughly similar to the frequencies observed for the whole observation period. Given the smaller sample size of this period of observation, larger oscillations in the percentages are expected, making the real trends difficult to identify. For the overall frequency of admission to ICU and all population groups observed, the frequency of admission to ICU was smaller for the months of April and May than for the full epidemic period (Figure **12**).

**a. All relevant data: Episodes with first hospitalization between Feb 26 2020 and May 31 2022**

**b. Apr & May: Episodes with first hospitalization between Apr 01 2022 and May 31 2022**

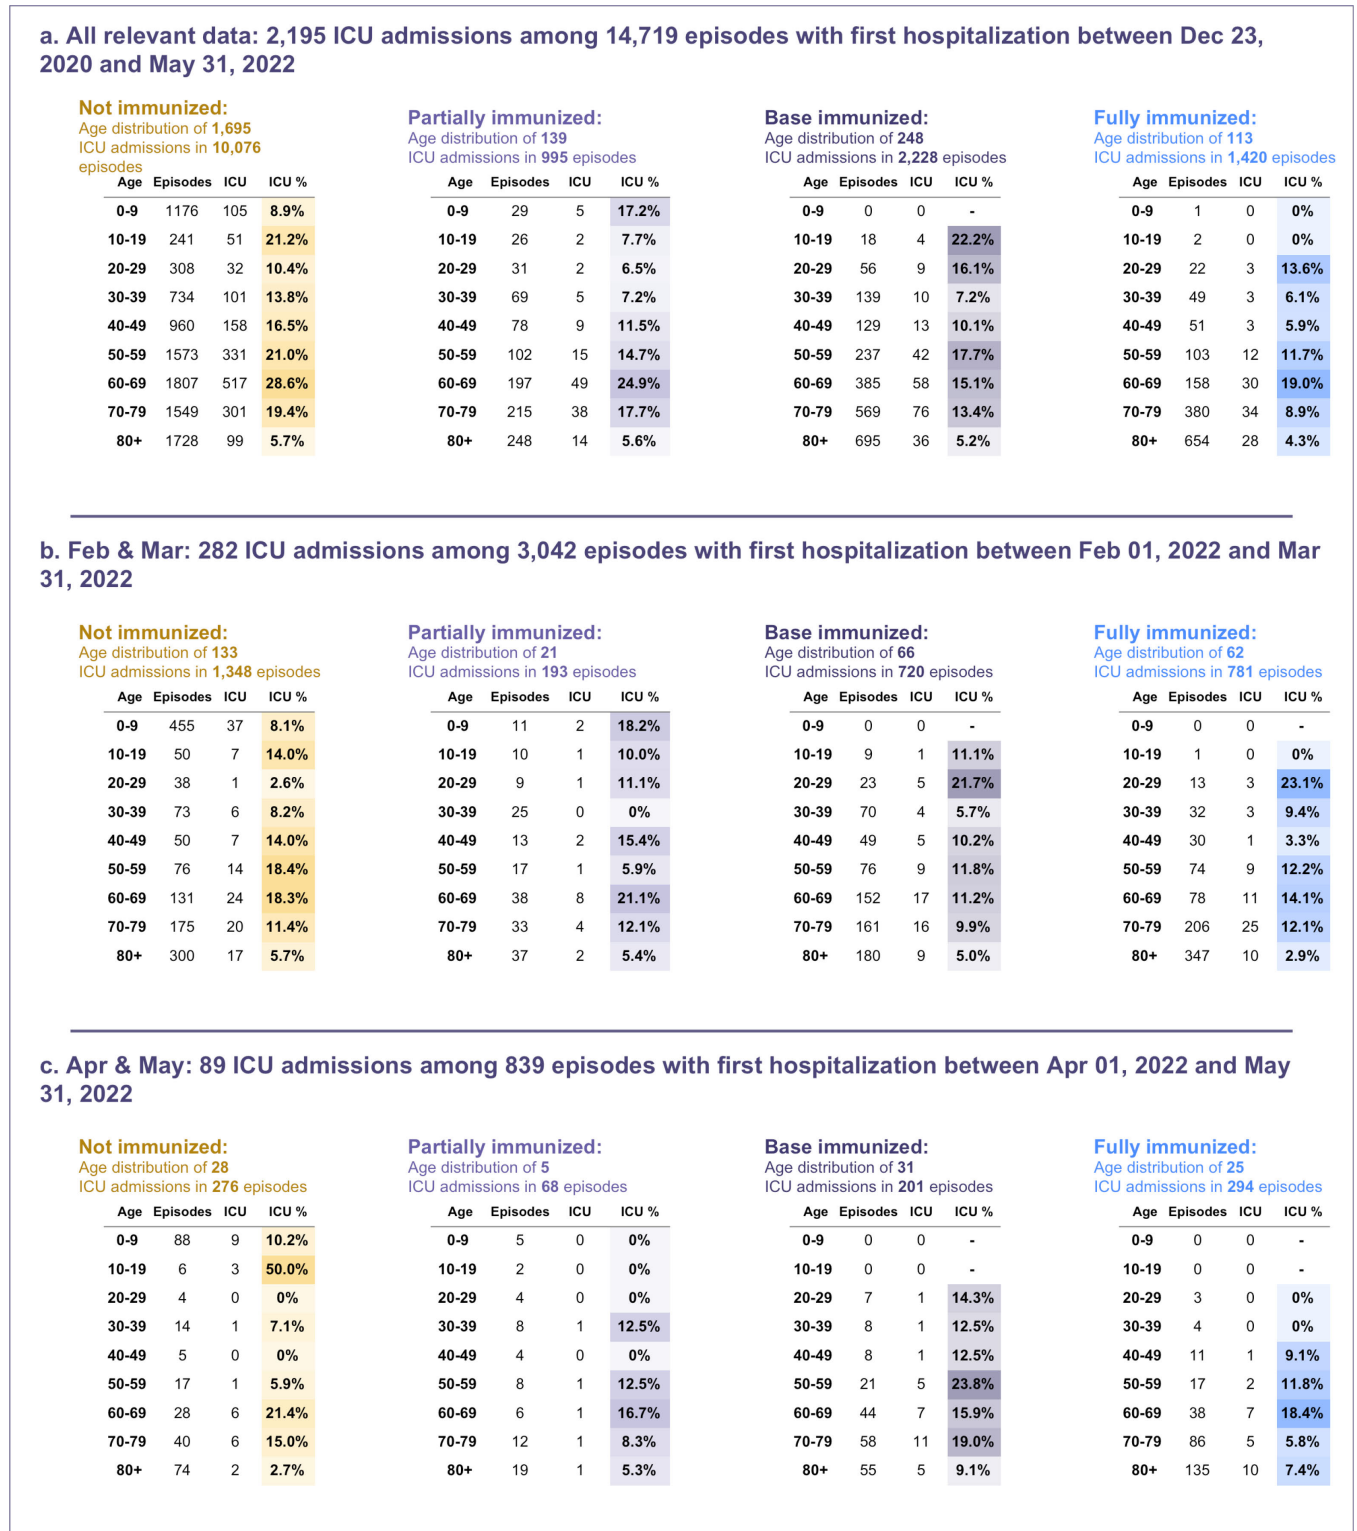

**Figure 12:** Percentage of hospitalization episodes with at least one ICU admission, grouped by demographic and risk factors, over two time intervals. For episodes with multiple hospitalizations, we considered whether they were admitted to the ICU during any of their hospitalizations. Both panels include records up to May 31, 2022 due to data completeness considerations. Records with incomplete data (ongoing episodes or with a pending outcome in the database) were not included. A blank row indicates a count of zero.

### 5.3. ICU admission rate by immune status

This figure (Figure 13) shows the ICU admission rate (number of episodes requiring an admission to the ICU over all episodes registered), stratified by age.

In recent data, from April and May, although episodes include 36.2% of people aged over 80 years old, these episodes did not have a high ICU rate (i.e. not many included an ICU stay).

**Figure 13:** ICU admission over all episodes of CH-SUR hospitalized patients by immune status and age group over three different periods. Episodes with missing age, missing gender, or missing were not included in the analysis. ICU

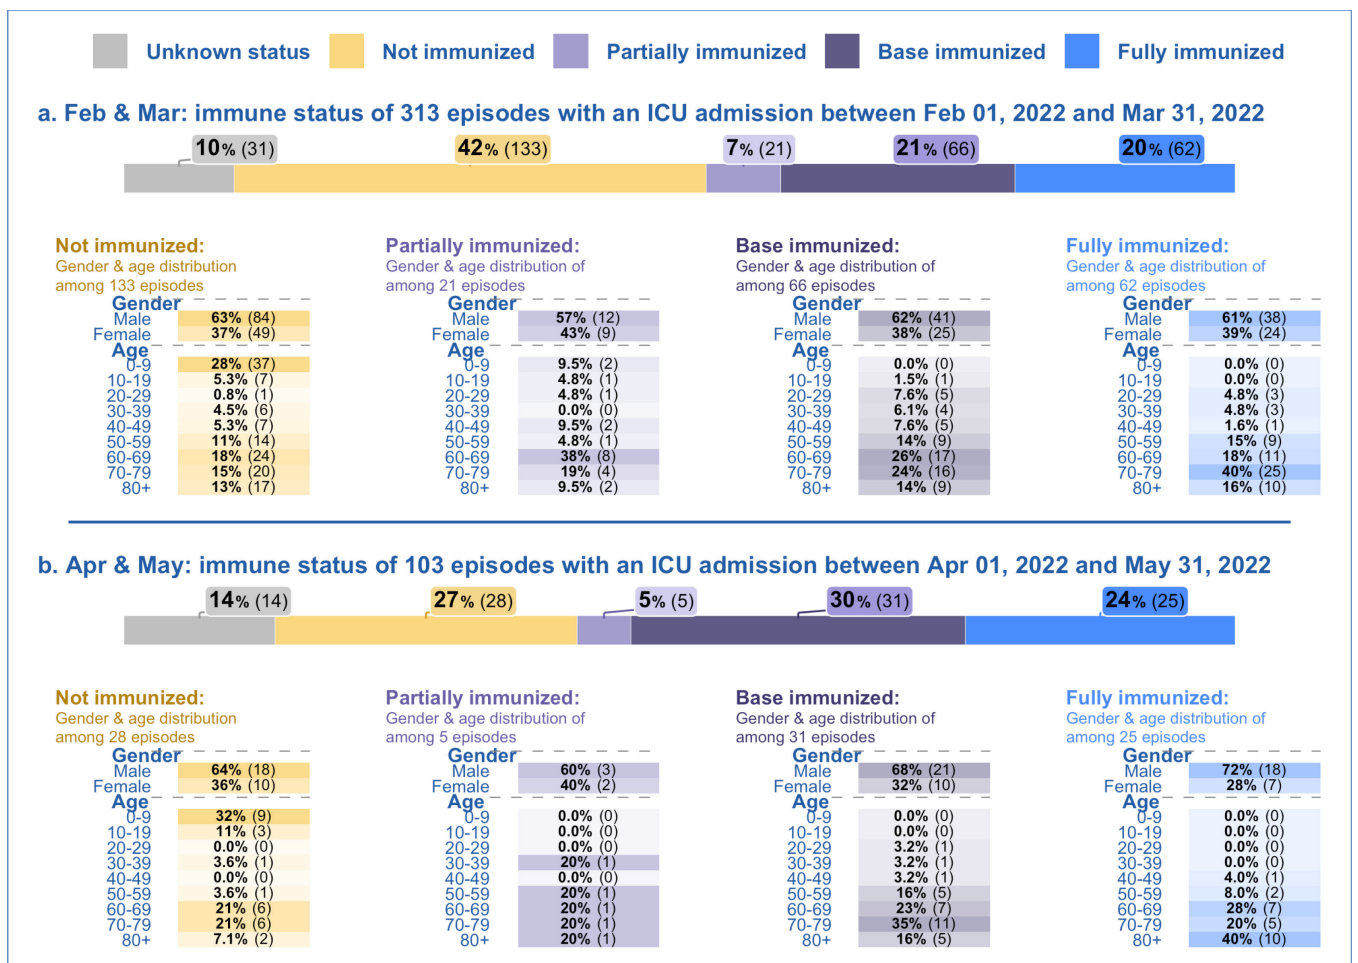

*admission rates (ICU%), especially for the partially immunized and fully immunized categories, should be interpreted with caution due to small sample sizes.*

## 5.4. ICU admissions contrasted by immune status

Due to a variance in vaccine coverage, only the recent evolution is represented. Data for June and July 2022 are not meaningful due to their **incompleteness** and are therefore not yet shown.

In both periods considered, the largest group of (**community acquired**) episodes with an ICU admission concerned non-immunized patients (42% and 27% of all episodes with ICU admissions in each of the described periods respectively). For most immune status categories shown and in both periods considered, there were more men than women admitted to the ICU (Figure 14).

For episodes of **fully immunized** patients, there is a skew towards older age groups being admitted to the ICU (between Feb 2022 and May 2022 around 91% of these episodes concerned patients aged 50+). In comparison, episodes of non-immunized patients admitted to the ICU included proportionally more patients from younger age groups, as only 57% (Feb, Mar) and 52.7% (Apr, May) of the episodes corresponded to patients aged 50 years and above.

**Figure 14:** Demographic characteristics of patients in ICU by immune status and episode, over two different periods. Episodes with a first admission date after May 31, 2022 were excluded, as a large proportion of these records have not been completely filled in the database. Episodes with missing ages or gender marked as 'Other' are not shown. Data on ICU admissions for the partially immunized and fully immunized categories should be interpreted with caution due to small sample sizes.

## 6. Comorbidities

Chronic cardiovascular disease, hypertension, chronic renal disease, diabetes, chronic respiratory disease, and immunosuppression <sup>1</sup> were chosen out of all comorbidities registered in CH-SUR <sup>2</sup>, to explore the risk factors tied to SARS-COV-2 hospitalization.

Most notably, episodes feature a predominance of males having a chronic cardiovascular disease comorbidity.

---

<sup>1</sup> Immunosuppression was defined as a patient having one or more of the following comorbidities: a hematological pathology with immuno-suppression, a rheumatological and auto-immune pathology with immuno-suppression, receiving a transplant (solid organs), and/or receiving an immuno-suppressive treatment.

<sup>2</sup> Chronic respiratory disease, Asthma, Diabetes, Hypertension, Chronic cardiovascular disease, Chronic renal disease, Chronic liver disease, Chronic neurological impairment, Hematological pathology with immuno-suppression, Oncological pathologies, Rheumatological and auto-immune pathology with immuno-suppression, Dementia, Transplant (solid organs), HIV-positive, Immuno-suppressive treatment, History of prematurity, Tuberculosis, Smoking, Obesity

## Incidence of comorbidities stratified by gender and age group among episodes from Feb 2020 to May 2022

**Figure 15:** Comorbidities incidence stratified by age group and by gender. Records with incomplete data for age or gender were not included. Data from the last two months was excluded due to potential data delay.

## 7. Comparison of Influenza and COVID-19

For their similarities and divergences, this section aims to put in comparison and contrast the hospitalizations of patients diagnosed with influenza and COVID-19. This section aims to compare the omicron variant of COVID characteristics to the most recent influenza season's characteristics. This section of the report focuses on community acquired infections (the investigation of nosocomial cases can be found in the subsequent section 7).

Figure 16 shows the episodes registered in CH SUR during the most recent influenza season (from week 44 2021 to week 22 2022), superimposed on the simultaneously registered COVID-19 episodes. Figure 17 explores the case fatality ratios of both diseases considering different demographic characteristics and hospitalization attributes of the patients hospitalized. Due to the differences in sample sizes, the outcomes should be compared with caution. During the period considered and in the hospitals included in this surveillance system, influenza had a lesser CFR than COVID-19 (1.7% compared to 4.3%), and was more lethal for women than for men (contrary to COVID-19). Similar to COVID-19, the CFR is higher for the older population (above 60 years old).

**Figure 16:** Influenza and COVID-19 episode counts per month over the most recent influenza season of 2021-2022.

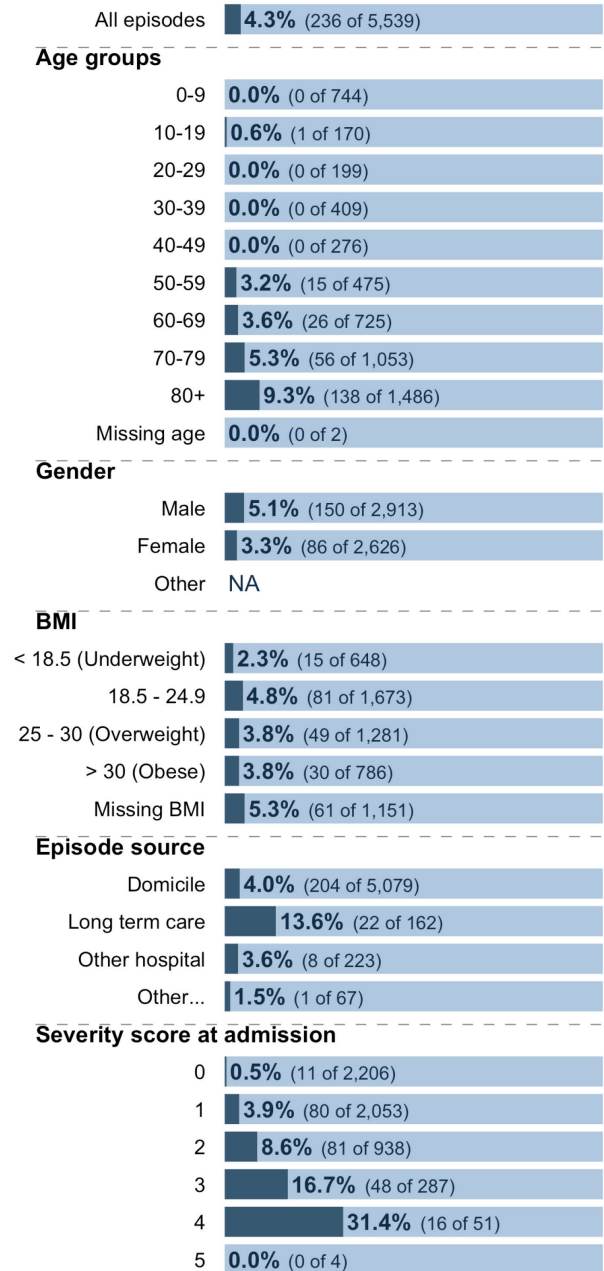

**a. Influenza CFR % for 903 episodes with first hospitalization between Nov 01 2021 and May 31 2022**

CFR % (deaths/episodes)

**b. COVID CFR % for 5,539 episodes with first hospitalization between Jan 10 2022 and May 31 2022**

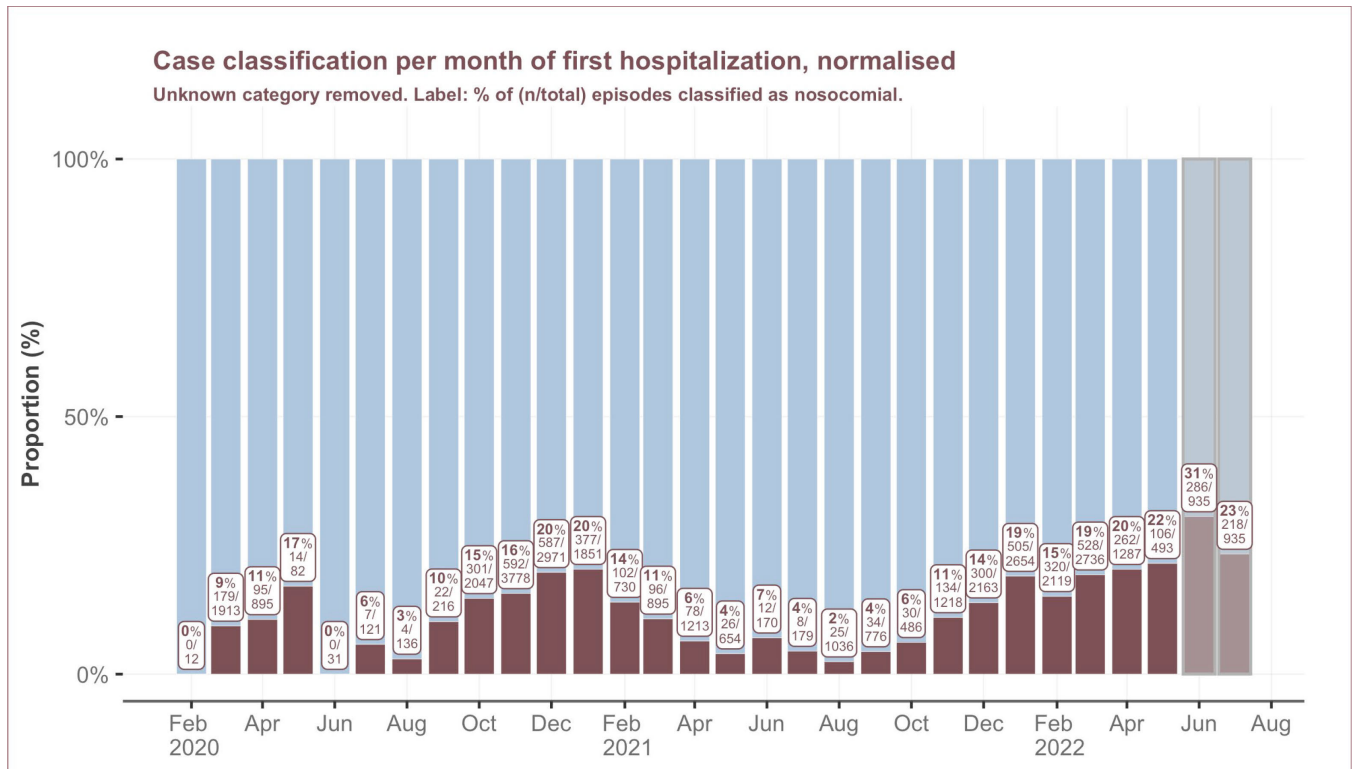

CFR % (deaths/episodes)

**Figure 17:** Comparison of demographics and hospitalization attributes for influenza (season 2021-2022) and COVID-19 (the beginning of the omicron-dominated time period up to recent data) for community acquired cases.

## 8. Nosocomial cases

The proportion of **episodes** with nosocomial infections peaked in January 2021 and again in March and April 2022: 20% or more of the episodes in these periods were linked to infections of nosocomial origin (Figure 18c). In recent months, this proportion rose since August 2021, accounting for 13.9% of the episodes registered in CH-SUR over the month of December 2021, 19.0% in January 2022, 19.3% in March 2022 and 20.4% in April 2022. This observation might be partially explained by periods of higher virus circulation and an increase in nosocomial systematic testing in some hospitals. However, changes in the testing strategy among hospitals are expected for the coming period, therefore, these data should be interpreted with caution.

**Figure 18:** Classification (infection source) of hospitalization episodes over time. Data from the last two months (highlighted gray) are considered provisional due to data entry delays.

Over the full course of the epidemic, the **nosocomial** infections affected principally an elderly population, with patients aged 80 years and above, accounting for 2,471 (47%) of the nosocomial episodes. In comparison, 7,286 (25%) of episodes with **community acquired** infections corresponded to patients aged 80 years and above. Possibly linked to this demographic characteristic, there were proportionally more deaths among the nosocomial compared to the community acquired episodes: 690 (13%) vs 2,442 (8.3%). (Figure 19)

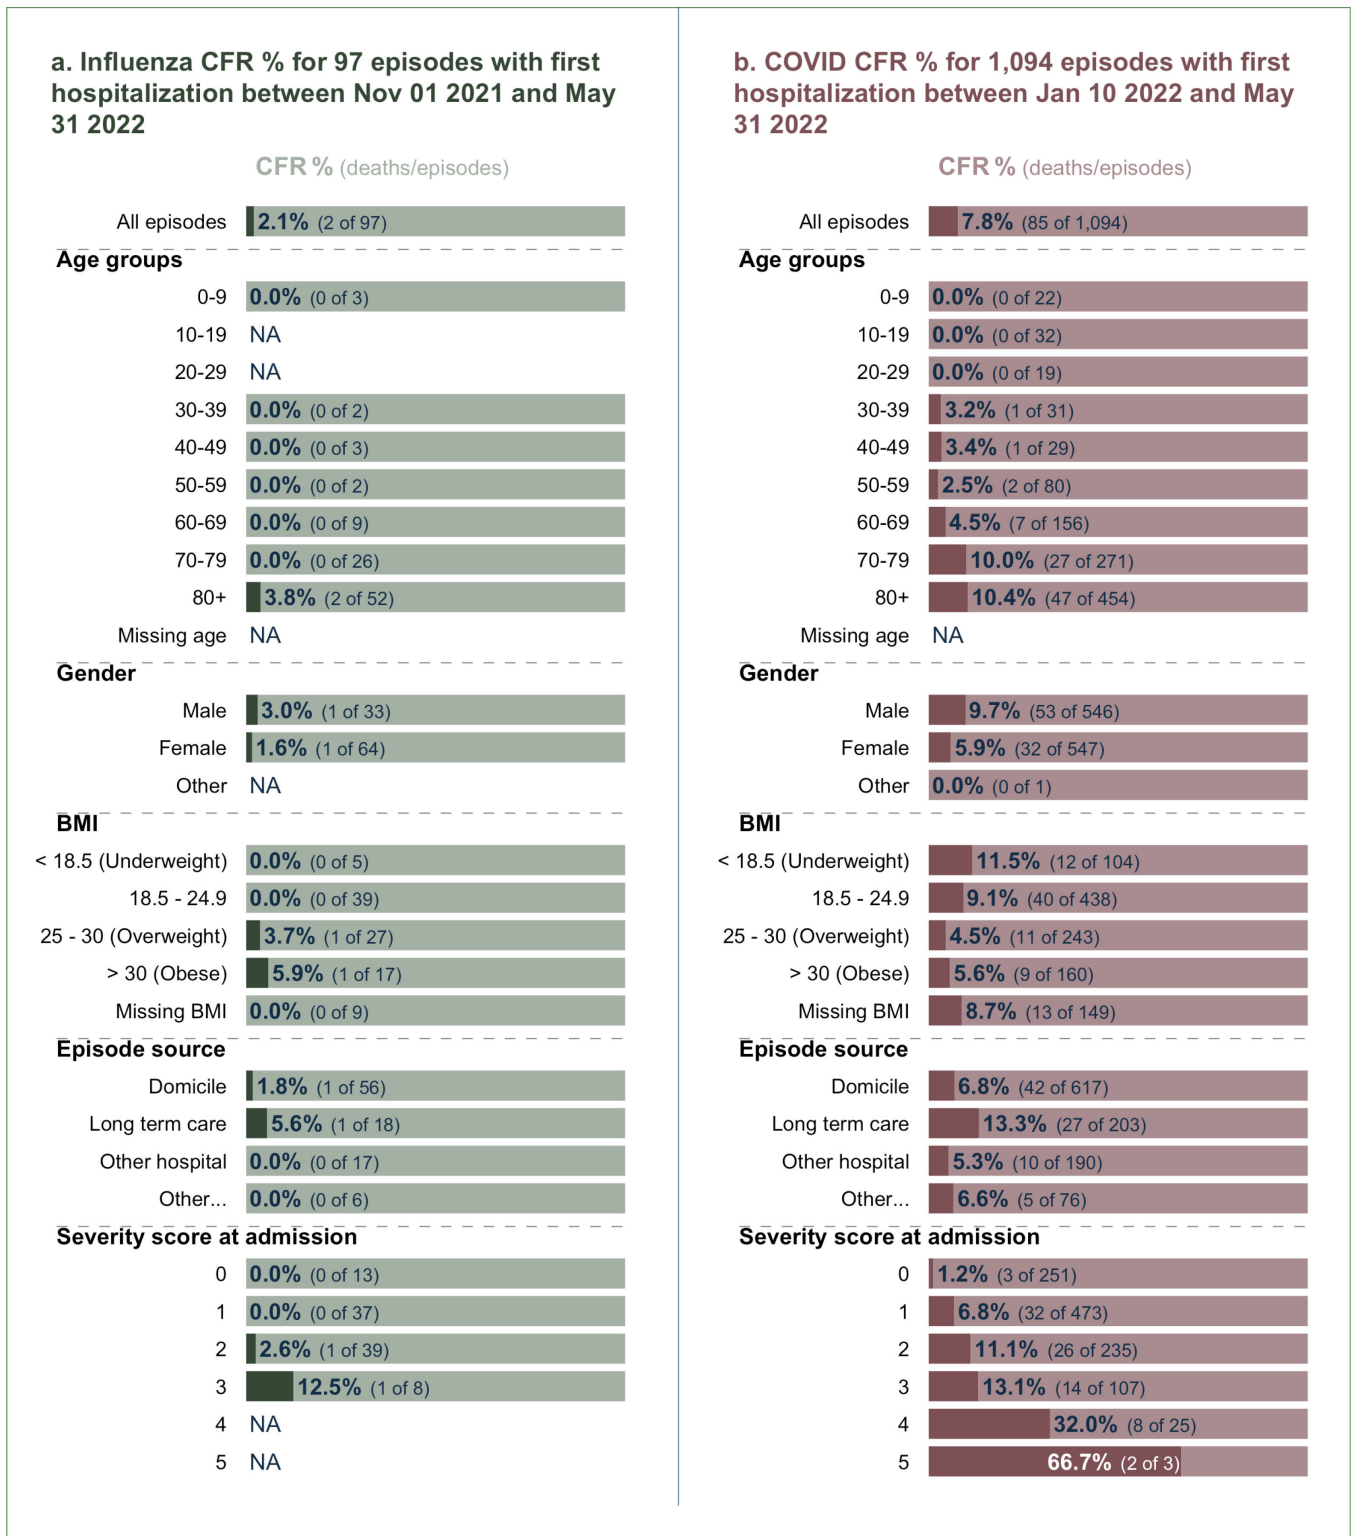

**ICU** admissions were slightly less common among episodes of patients with nosocomial infections, when compared to community-acquired infections (Figure 19). Another noteworthy difference lies in the treatments administered. During community acquired episodes a corticosteroid treatment was administered more frequently than during nosocomial episodes: the treatment was administered in 11,039 (37%) episodes with community acquired infection and in 1,108 (21%) nosocomial episodes.

## Community acquired and nosocomial episodes from Feb 2020 to Jul 2022

**Figure 19:** Case classification (infection source) of hospitalization episodes Comparison of community acquired and nosocomial cases by demographics, severity score, ICU, outcomes and treatments.

Figure 20 displays the characteristics and CFR of nosocomial episodes for influenza compared to the characteristics of nosocomial episodes for COVID-19: the small number of nosocomial cases for influenza occur in an elderly population (70 and above). Similar to the comparison for community acquired episodes in Figure 17, here the focus is on nosocomial episodes.

**Figure 20:** Comparison of demographics and hospitalization attributes for influenza (season 2021-2022) and COVID-19 (the beginning of the omicron-dominated time period up to recent data) for nosocomial cases. Due to very small sample sizes, these data should be handled with caution.

## 9. Glossar und ergänzende Informationen

### **Hospitalization / Hospitalisation:**

Bei der Hospitalisation handelt es sich um die kleinste Datenanalyseeinheit. Sie ergibt sich aus jeweils einem Ein- und Austritt in einem an CH-SUR teilnehmenden Spital, wenn der Aufenthalt länger als 24 Stunden andauert. Jede Aufnahme einer Person in ein Spital wird als neue Hospitalisation gezählt. Da es innerhalb desselben Krankheitsverlaufs (einer einzelnen Infektion) häufig zu mehreren Hospitalisationen (Wiedereintritten) kommt, erfolgt die Analyse in diesem Bericht anhand der Anzahl Episoden und nicht anhand der Anzahl Hospitalisationen.

### **Episode / Episode:**

Bei jeder Neuaufnahme in ein Spital, die mindestens 30 Tage nach einer früheren Hospitalisation erfolgt und zu einem Aufenthalt von mehr als 24 Stunden führt, wird eine Episodennummer vergeben. Wird eine Person innerhalb von 30 Tagen nur einmal oder mehrfach hospitalisiert, wird in beiden Fällen nur eine Episode gezählt. Wird eine Person im Abstand von über 30 Tagen zweimal hospitalisiert, werden zwei unterschiedliche Episodennummern vergeben. Wird eine Person innerhalb von 30 Tagen nach der letzten Entlassung zwischen zwei an CH-SUR teilnehmenden Spitälern transferiert, werden diese Hospitalisationen zur selben Episode gezählt. Eine Episode kann deshalb mehrere Hospitalisationen und jede Hospitalisation kann mehrere IPS-Aufnahmen umfassen.

### **Reason for the hospitalization / Hospitalisationsgrund:**

- *Hospitalization because of COVID-19 / Hospitalisation aufgrund von COVID-19:* Basierend auf den bei der Aufnahme verfügbaren Informationen wird die Person hospitalisiert, weil sie Symptome aufgrund von COVID-19 aufweist oder an einer offensichtlich durch COVID-19 verursachten Dekompensation einer chronischen Krankheit leidet.
- *Hospitalization with a SARS-CoV-2 infection / Hospitalisation mit einer SARS-CoV-2-Infektion:* Basierend auf den bei der Aufnahme verfügbaren Informationen weist die Person einen positiven SARS-CoV-2-Test auf, wird aber ohne COVID-19-Symptome aus einem nicht mit COVID-19 zusammenhängenden Grund hospitalisiert. Das Hauptproblem ist also ein Unfall oder eine Erkrankung, die nicht mit COVID-19 in Verbindung steht.

### **Origin of the infection / Infektionsursprung:**

- *Community acquired infection: / Ambulant erworbene Infektion:* Die SARS-CoV-2 Infektion wurde vor der Aufnahme in das Spital oder innerhalb der ersten fünf Tage nach der Aufnahme festgestellt.
- *Nosocomial infection / Nosokomiale Infektion:* Eine Episode gilt als «nosokomial», wenn die SARS-CoV-2 Infektion nach fünf oder mehr Tagen nach der Aufnahme in das Spital festgestellt wird.

### **Severity score at admission / Schweregrad bei der Aufnahme:**

Bei Erwachsenen wird zur Beurteilung des Schweregrads der CURB-65 Score angewendet. Für jedes der folgenden Kriterien wird jeweils 1 Punkt gezählt: Verwirrtheit (Abbreviated Mental Test Score < 9), Serumharnstoff > 19 mg/dl, Atemfrequenz > 30 pro Minute, tiefer Blutdruck (diastolisch < 60 oder systolisch < 90 mmHg), Alter > 65 Jahre. Bei Kindern wird je ein Punkt für folgende Kriterien gezählt: Atemnot, Sauerstoffsättigung < 92%, Anzeichen schwerer klinischer Dehydratation oder eines klinischen Schocks und ein veränderter Bewusstseinszustand. Der Schweregrad entspricht der Summe der jeweiligen gezählten Punkte.

**Intermediate care unit (intermediate care or IMC) / Intermediate Care Unit (IMC):** Pflegestation für Personen, die an einer Störung einer lebenswichtigen Funktion leiden oder deren Pflegelast keine Rückkehr in eine Bettenstation erlaubt. Die Intermediate Care Unit bildet das Bindeglied zwischen Intensivpflegestation und Bettenstation.

**Intensive care unit (ICU) / Intensivpflegestation (IPS):** Pflegestation für Personen, die eine schwerwiegende Störung einer oder mehrerer lebenswichtiger Funktionen haben oder bei denen das Risiko schwerer Komplikationen besteht.

### **Immune status / Immunstatus:**

Für die Definition des Immunstatus werden sowohl die Impfung als auch eine frühere bestätigte SARS-CoV-2-Infektion berücksichtigt. Der Immunstatus ist wie folgt definiert:

a) *Not immunized / Nicht immunisiert*: Personen, die zum Zeitpunkt des positiven SARS-CoV-2-Tests keine Dosis irgendeines Impfstoffs erhalten hatten und bei denen kein Nachweis einer Infektion mit dem Virus vor der Hospitalisationsepisode bestand.

b) *Partially immunized / Teilweise immunisiert*:

1. Personen, die vor dem positiven Test eine Impfstoffdosis Moderna (Spikevax®), Pfizer/BioNTech (Comirnaty®), AstraZeneca (Vaxzevria®), Sinopharm®, Sinovac (CoronaVac®) oder COVAXIN® erhalten hatten und bei denen kein Nachweis einer früheren SARS-CoV-2-Infektion bestand.
2. Personen, die mit keiner Dosis geimpft wurden und bei denen eine frühere SARS-CoV-2-Infektion bestätigt wurde, die in der Vergangenheit eine Hospitalisation erfordert hatte oder nicht; unabhängig von der Zeit seit der früheren Infektion. Achtung: Viele genesene Personen werden in der Datenbank nicht als solche identifiziert (erst seit Juni 2021 erhobene Information, nicht diagnostizierte Infektionen, fehlende Informationen im Dossier).

c) *Base immunized / Grundimmunisiert*:

1. Personen, die eine Dosis des Impfstoffs Johnson & Johnson (Janssen®) oder zwei Dosen des Impfstoffs Spikevax®, Comirnaty®, Vaxzevria®, Sinopharm®, CoronaVac® oder COVAXIN® erhalten hatten (Impfempfehlung BAG / Eidgenössische Kommission für Impffragen).
2. Personen mit einer dokumentierten früheren Infektion oder einem positiven Test (die einen Spitalaufenthalt erfordert hatten oder nicht), die eine Dosis eines der oben aufgeführten Impfstoffe erhalten hatten, unabhängig von der Zeit seit der Genesung, dem Datum und der Marke des Impfstoffs, und einem positiven Test oder einer Hospitalisation.
3. Personen, die eine Kombination folgender Impfstoffe erhalten hatten: Comirnaty® und Spikevax®, Vaxzevria® und Comirnaty® oder Vaxzevria® und Spikevax®. Personen, die eine zusätzliche Auffrischimpfung erhalten hatten, werden hier nicht berücksichtigt (Kategorie Fully immunized / Vollständig immunisiert).

d) *Fully immunized / Vollständig immunisiert*: Grundimmunisierte Personen, die eine oder mehrere weitere Impfdosen (Auffrischimpfung) erhalten hatten, unabhängig von der Zeit seit der letzten Impfung (mindestens 4 Monate nach der letzten Impfung).

e) *Unknown immune status / Unbekannter Immunstatus*: Personen, für die keine Informationen über Impfungen und zur Immunität vorlagen.

**Discharge / Entlassung**: Ein Spitalaustritt gilt als «Entlassung», wenn die Person das Spital mit einem der folgenden Zielorte verlässt: 1. nach Hause; 2. Langzeitpflegeeinrichtung; 3. anderes Spital; 4. andere Einrichtung, die sich nicht am CH-SUR-Überwachungssystem beteiligt; 5. Rehabilitationseinrichtung; 6. unbekannter Zielort

**Reason of death / Todesursache**: Personen, bei denen COVID-19 die Todesursache war (died of COVID-19 / verstorben an COVID-19), werden getrennt aufgeführt von den COVID-19-Patientinnen und -Patienten, die wegen anderer Todesursachen verstarben (died with COVID-19, but not of COVID-19 / verstorben mit COVID-19, aber nicht an COVID-19). Ob eine Person an COVID-19 oder aus einem anderen Grund verstarb, wird auf Spitalebene im betreffenden am CH-SUR-System teilnehmenden Zentrum von einer Ärztin oder einem Arzt beurteilt. Fälle, in denen die Todesursache nicht sicher ist, aber eine COVID-19-Diagnose vorliegt (in Übereinstimmung mit den Einschlusskriterien für CH-SUR), werden als «verstorben an COVID-19» oder «vermuteter COVID-19-Todesfall» gezählt.

**Dealing with missing data / Umgang mit fehlenden Daten**: Wenn im Text erwähnt, werden fehlende Daten von der Analyse ausgeschlossen. Andernfalls werden Datensätze mit fehlenden Daten in der Gesamtanzahl berücksichtigt und entsprechend analysiert. Dies kann dazu führen, dass die Denominatoren der verschiedenen analysierten Kategorien nicht dieselbe Gesamtsumme ergeben. In einigen Abbildungen werden die Daten der letzten beiden Monate aufgrund von Verzögerungen bei der Datenerfassung als provisorisch betrachtet und grau markiert, wobei dies jeweils angegeben wird.
